

Analysis of Algorithms II

Recitation Week-7

2022-2023 Spring

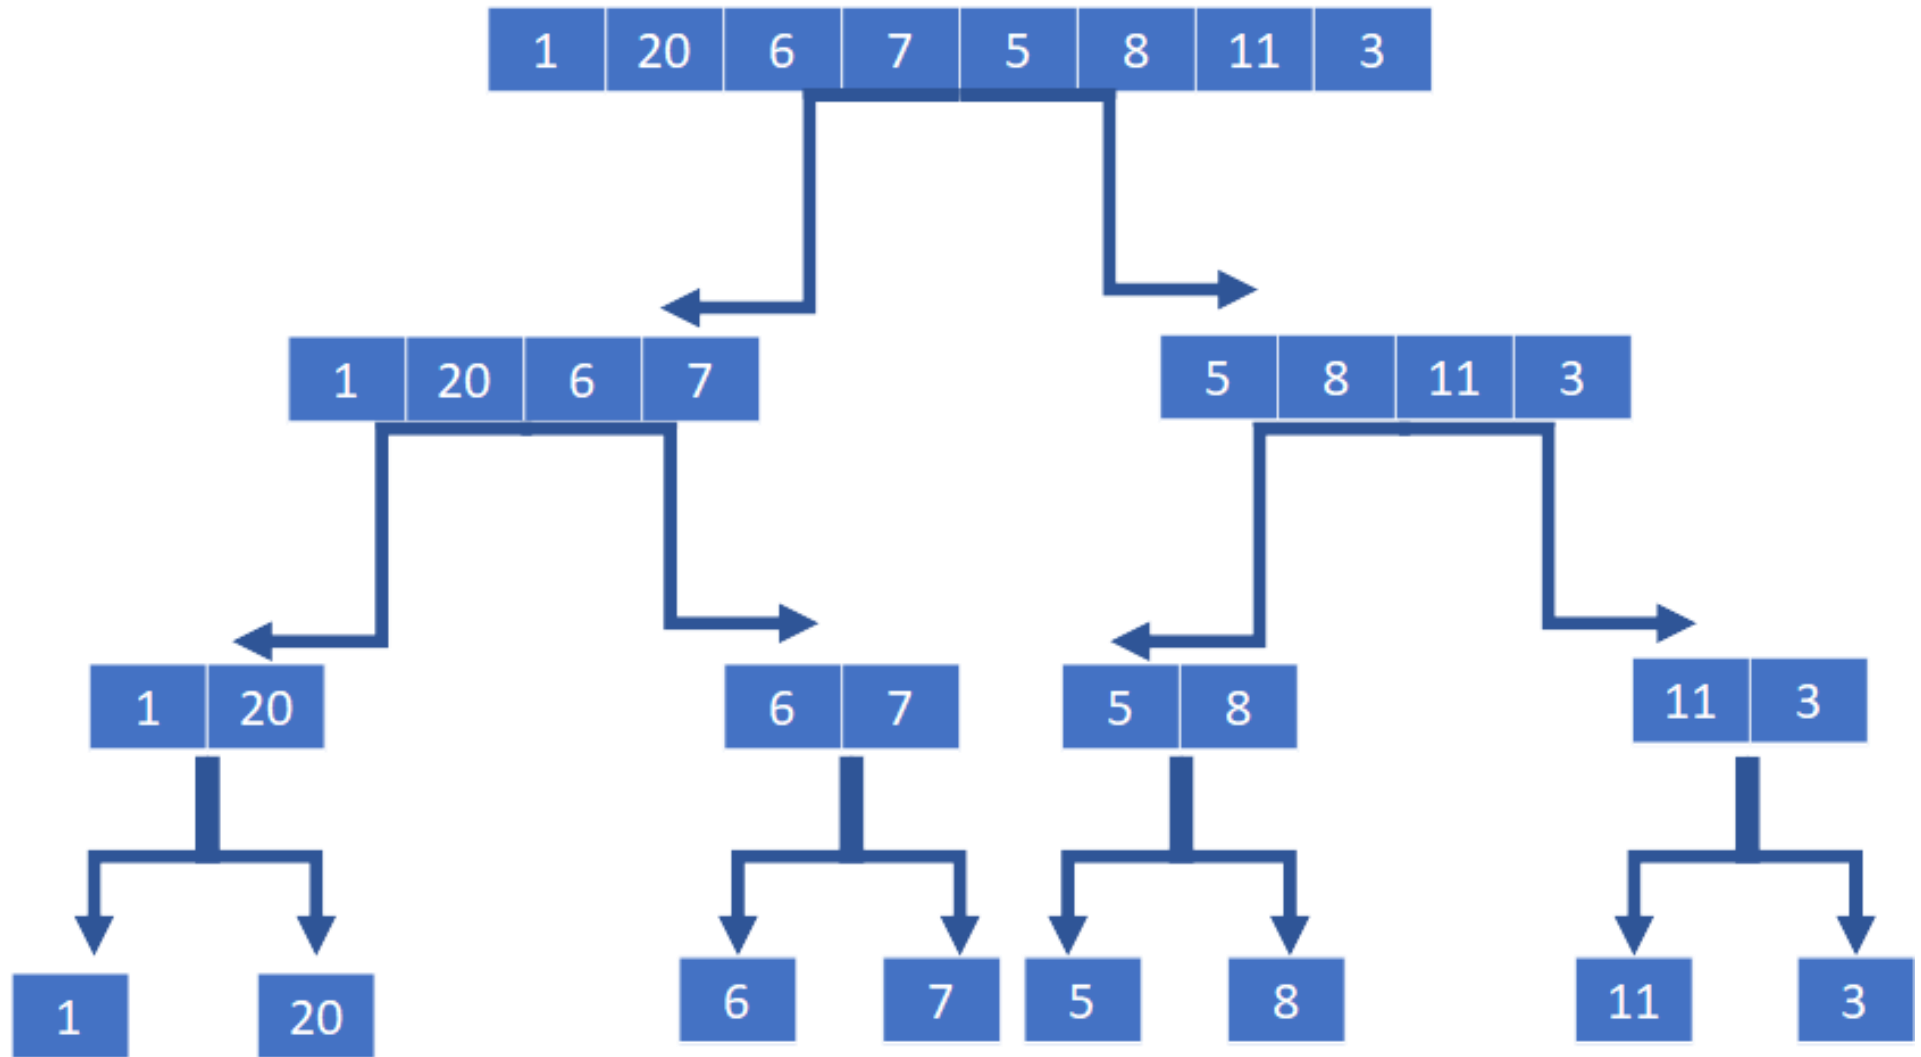

Q1) Count the number of inversions for the given numbers; 1, 20, 6, 7, 5, 8, 11, 3. Use divide and conquer (DnC) approach.

Q1)Count the number of inversions for the given numbers; 1, 20, 6, 7, 5, 8, 11, 3. Use divide and conquer (DnC) approach.

Direct approach -> Modify Bubble-Sort

DnC approach -> Modify Merge-Sort

Partition

Merging step

Convex-Hull Problem

- For a given point cloud, the goal is to find the polygon with minimum sides that contains all points on or within the polygon.
- Informally you can think of it as you pound some nails into some wood. You use a rubber band to wrap all the nails from the outside. The rubber band forms the asked polygon.
- There are both iterative (Graham Scan, Jarvis March) and DnC approaches (normal, Quick-Hull).

Q2) Analyze (normal) DnC approach using point cloud below

Q2-A) Normal Approach

Partition like Merge-Sort;

- Sort points regarding x-coordinates
- To find division lines, use median of medians algorithm

Merge two convex-hulls by finding the upper and lower tangent lines.

How to find them?

For now, just add one point to a convex-hull

If you look at the relationship between the line, previous and next vertices (points on the current polygon); you can observe;

- If both previous and next vertices stay below to the line -> upper tangent
- If both previous and next vertices stay upper to the line -> lower tangent

Now, merge the sub-convex-hulls;

- For the left sub-convex-hull, find the rightmost vertex
- For the right sub-convex-hull, find the leftmost vertex
- Alternately find the tangent lines until reached by changing the vertices

For now, just find the upper tangent

next is above, prev is below
-> select next as pivot

Both are below, we found an
upper-tangent for right polygon

next is above, prev is below
-> select next as pivot

Both are below, we found
an upper-tangent for left polygon

next is above, prev is below
-> select next as pivot

Both are below, we found
an upper-tangent for right polygon

next is above, prev is below
-> select next as pivot

Both are below, we found an upper-tangent for left polygon

As this line is upper tangent for both polygons, we can end our search

After finding the lower tangent in a similar manner, we can connect two sub-convex-hulls.

Do not forget discarding inner (old) edges

The final polygon is

$$T(n) = 2T(n/2) + O(n) \rightarrow O(n \log n)$$
